

Appendix 1: Inventory Design and Methods

The Pacific Northwest Research Station's (PNW) Forest Inventory and Analysis (FIA) Program implemented the new annual inventory in California in 2001. The overall sampling design is a significant change from that of previous periodic inventories; the differences are discussed more fully below.

In the annual inventory system for the Pacific Northwest (coastal Alaska, Washington, Oregon, and California), the objective is to measure approximately 10 percent of the plots across an entire state each year. This annual subsample is referred to as a panel. The plots measured in a single panel are selected to ensure systematic coverage within each county, spanning both public and privately owned forests, and including lands reserved from industrial wood production such as national parks, wilderness areas, and natural areas.

Estimates of forest attributes can be derived from measurements of a single panel for areas as small as a survey unit or ecosection; however, such estimates are often imprecise because one panel represents only 10 percent of the full inventory sample. More-precise statistics are obtained by combining data from multiple panels. After at least 60 percent of plots have been sampled, change can be estimated through a comparison of average values across different sets of panels. Estimates from sampled plots in the five panels measured from 2001 to 2005 were combined to produce the statistics in this report. When all panels have been measured once (2010), each panel will be remeasured at 10-year intervals.

The FIA Program collects information in three phases. In phase 1, a sample of points is interpreted from remotely sensed imagery (either aerial photos or satellite data) and the landscape is stratified into meaningful groupings, such as forested and nonforested areas, ecologically similar regions, and forest types. In phase 2, field plots are measured for a variety of indicators that describe forest composition, structure, and the physical geography of the landscape. Phase 2 plots are spaced at approximate 3-mile intervals on a hexagonal grid throughout the forest. In phase 3, one of every 16 phase 2 field plots is visited and a variety of forest health measurements are taken.

Phase 1

The goal of phase 1 is to reduce the variance associated with estimates of forest land area and volume. Digital imagery collected by remote-sensing satellites is classed into a few similar strata (such as forest or nonforest) by means of standard techniques for image classification, and the total area of each of these strata is used to assign a representative acreage to each sample plot. Source data were derived from Landsat Thematic Mapper (98.4 feet resolution) imagery collected between 1990 and 1992. An image-filtering technique is used to classify individual plots through a summary of the 5- by 5-pixel region that surrounds the pixel containing a sample plot. The resulting 26 classes, or strata (ranging from entirely forested to entirely nonforested, for example), are combined with other geographic attributes likely to improve stratification effectiveness, such as owner class. The resulting strata are evaluated for each estimation unit (county, or combination of small counties), and collapsed as necessary to ensure that at least four plots are in each stratum. Stratified estimation is applied by assigning each plot to one of these collapsed strata and by calculating the area of each collapsed stratum in each estimation unit. The estimates of area and volume from stratified data are usually more precise than those from unstratified estimates.

Phase 2

The plot installed at each forested phase 2 location is a cluster of four subplots spaced 120 feet apart (fig. 89). Subplot 1 is in the center, with subplots 2 through 4 uniformly distributed radially around it. Each point serves as the center of a 1/24-acre circular subplot used to sample all trees at least 5.0 inches in diameter at breast height (d.b.h.). A 1/300-acre microplot, with its center located just east of each subplot center, is used to sample trees 1.0 to 4.9 inches d.b.h., as well as seedlings (trees less than 1.0 inch d.b.h.). On national forests in California, a hectare plot (a 185.1-foot fixed-radius plot centered on subplot 1) is also established to tally trees larger than 32 inches d.b.h. in the eastern part of the Northwest Forest Plan area and larger than 48 inches d.b.h. in the western part of the Northwest Forest Plan area.

All phase 2 plots identified by aerial photography as possibly being forested are established in the field without

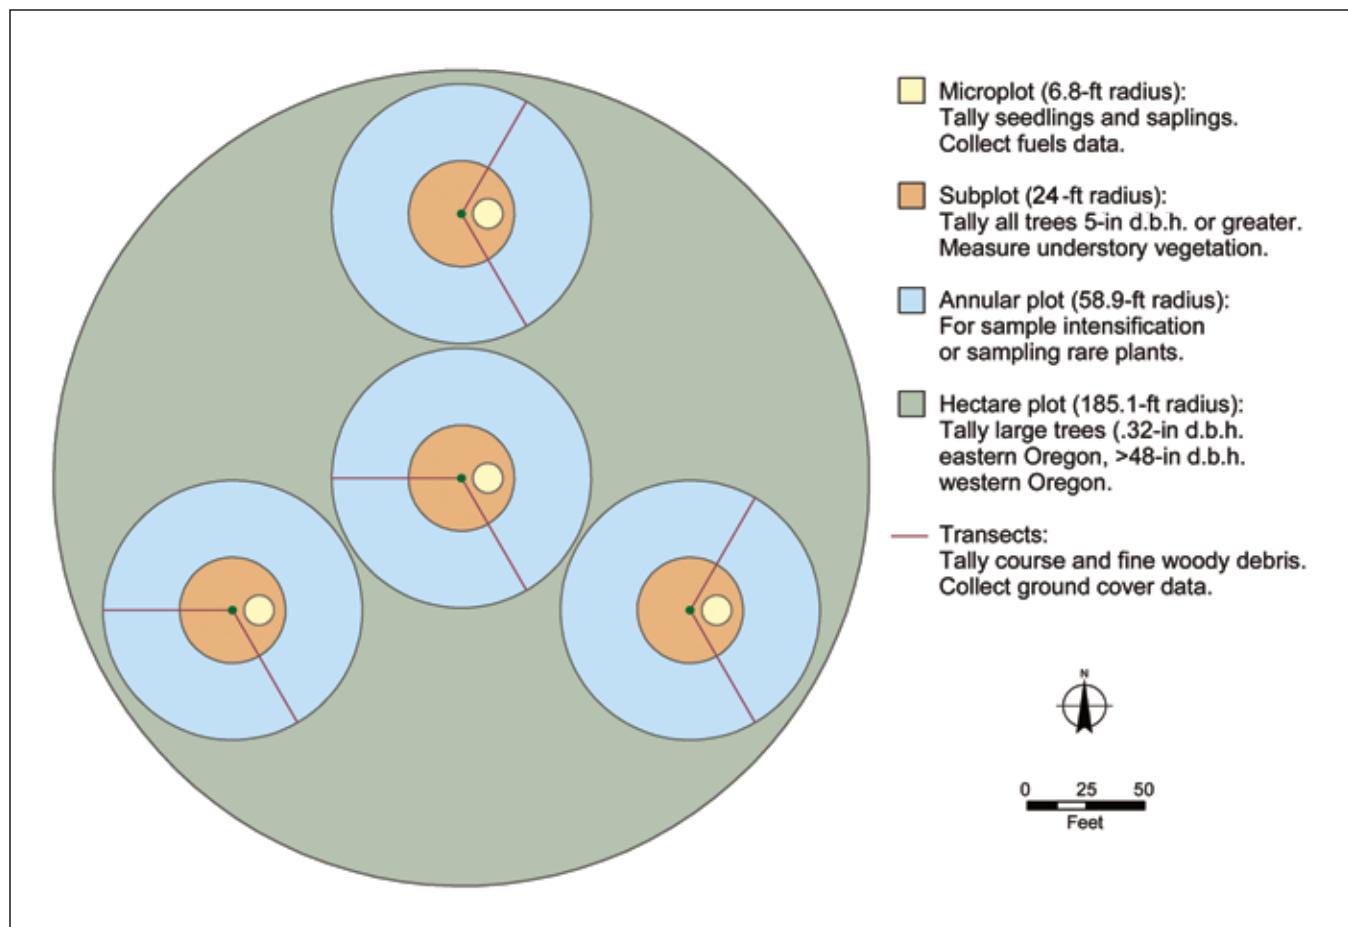

Figure 89—The Forest Inventory and Analysis plot design used in California, 2001–2005.

regard to land use or land cover. Field crews delineate areas that are comparatively less heterogeneous than the plot as a whole with regard to reserved status, owner group, forest type, stand size class, regeneration status, and tree density; these areas are described as condition classes. The process of delineating these condition classes on a fixed-radius plot is called mapping. All measured trees are assigned to the mapped condition class in which they are located.

On phase 2 plots, crews assess physical characteristics such as slope, aspect, and elevation; stand characteristics such as age, size class, forest type, disturbance, site productivity, and regeneration status; and tree characteristics such as tree species, diameter, height, damages, decay, and vertical crown dimensions. They also collect general descriptive information such as soil depth, proximity to water and roads, and the geographic position of the plot

in the larger landscape. In California, crews also assess height and cover of understory species, the structure of live and dead fuels, and the structure and composition of down wood as regional variables (see “Core, Core-Optional, and Regional Variables” section below).

The FIA Program sampled 3,542 forested phase 2 plots in California between 2001 and 2005. Estimates of timber volume and other forest attributes were derived from tree measurements and classifications made at each plot. Volumes for individual tally trees were computed with equations for each of the major species in California. Estimates of growth, removals, and mortality were determined from measurements taken at approximately 1,900 permanent sample plots established in the previous inventory and in conjunction with increment cores taken during the annual inventory.

Phase 3

More-extensive forest health measurements are collected in a 16-week period during the growing season (when most plants are in full leaf and many are flowering) on a subset (1/16) of phase 2 sample locations. At the phase 3 plots, measurements are taken on tree crowns, soils, lichens, downed woody material, and understory vegetation, in addition to the phase 2 variables. One forest health measurement, ozone injury, is conducted on a separate grid with all 65 ozone plots measured annually. The FIA Program sampled 351 forested phase 3 plots in California between 2001 and 2005. The relatively small number of phase 3 samples is intended to serve as a broad-scale detection monitoring system for forest health problems.

Core, Core-Optional, and Regional Variables

The majority of FIA variables collected in California are identical to those collected by FIA elsewhere in the United States—these are national “core” or “core optional” variables (as the name suggests, collection of core optional variables is optional but, if collected, they must be collected in the same way everywhere). A number of other variables are unique to PNW-FIA. These are “regional” variables and include such items as down woody material and understory vegetation on phase 2 plots (not to be confused with down woody and understory vegetation on phase 3 plots, which are measured using a slightly different protocol), as well as insect and disease damage, a record of previous disturbance on the plot, and measurements for special studies (such as nesting habitat assessment for the marbled murrelet (*Brachyramphus marmoratus*)).

Data Processing

The data used for this report are stored in the FIA National Information Management System (NIMS). It provides a means to input, edit, process, manage, and distribute FIA data. NIMS includes a process for data loading, a national set of edit checks to ensure data consistency, an error correction process, approved equations and algorithms, code to compile and compute calculated attributes, a table report generator, and routines to populate the presentation database. NIMS applies numerous algorithms and equa-

tions to calculate, for example, stocking, forest type, stand size, volume, and biomass. NIMS generates estimates and associated statistics based on county areas and stratum weights developed outside of NIMS. Additional FIA statistical design and estimation techniques are further reviewed in Bechtold and Patterson (2005).

Statistical Estimates

Throughout this report we have published standard errors (SE) for most of our estimates. These standard errors account for the fact that we measured only a small sample of the forest (thereby producing a sample-based estimate) and not the entire forest (which is the population parameter of interest). Because of small sample sizes or high variability within the population, some estimates can be very imprecise. The reader is encouraged to take the standard error into account when drawing any inference. One way to consider this type of uncertainty is to construct confidence intervals. Customarily, 66-percent or 95-percent confidence intervals are used. A 95-percent confidence interval means that one can be 95 percent confident that the interval contains the true population parameter of interest. For more details about confidence intervals, please consult Moore and McCabe (1989) or other statistical literature.

It is relatively easy to construct approximate 66-percent or 95-percent confidence intervals by multiplying the SE by 1.0 (for 66-percent confidence intervals) or 1.96 (for 95-percent confidence intervals) and subtracting and adding this to the estimate itself. For example, in table 2 of appendix 2, we estimated the total timberland in California to be 19,551 thousand acres, with a SE of 266. A 95-percent confidence interval for the total timberland area ranges from 19,030 to 20,072 thousand acres.

The reader may want to assess whether or not two estimates are significantly different from each other. The statistically correct way to address this is to estimate the SE of the difference of two estimates and either construct a confidence interval or use the equivalent z-test. However, this requires the original inventory data. It is often reasonable to assume that two estimates are nearly uncorrelated. For example, plots usually belong to one and only one owner. The correlation between estimates for different

owners will be very small. If both estimates are assumed to be nearly uncorrelated, the standard error of the difference can be estimated by

$$SE_{Difference} = \sqrt{SE_{Estimate\ 1}^2 + SE_{Estimate\ 2}^2}$$

Using the SE of the difference, a confidence of the difference can be constructed with this method.

If two estimates are based on data that occur on the same plot at the same time, the above equation should not be used. For example, table 17 in appendix 2 contains estimates of tree volume by diameter class. If one wants to compare the volume of trees in the diameter class 9.0 to 10.9 d.b.h. (9,676 million board feet) with that of trees in the diameter class 21.0 to 22.9 d.b.h. (21,484 million board feet), the covariance between the estimates is not zero, and this equation should not be used.

There are two other approaches the reader could consider, but we do not recommend them. The first is to construct a confidence interval for **one** estimate and evaluate whether the other estimates falls within the interval. The problem is that unless both estimates are **highly positively** correlated, this approach will lead to a too-small confidence interval. The second approach is to construct confidence intervals for **both** estimates and determine whether or not they overlap. The problem here is that unless both estimates are highly negatively correlated, this approach will be very conservative. For more complex and indepth analysis, the reader may contact the PNW-FIA Program.

All estimates—means, totals and their associated SE—are based on the poststratification methods described in detail by Bechtold and Patterson (2005).

Access Denied, Hazardous, or Inaccessible Plots

Although every effort was made to visit all field plots that were entirely or partially forested, some were not sampled for a variety of reasons. Field crews may have been unable to obtain permission from the landowner to access the plot (“denied access”), and some plots were impossible for crews to safely reach or access (“hazardous/inaccessible”). Some

private landowners deny access to their land. Although permission to visit public lands is almost always granted, some public land lies in higher elevation areas with extreme topography that can be very difficult or impossible to reach.

This kind of missing data can introduce bias into the estimates if the nonsampled plots tend to be different from the entire population. Plots that are obviously nonforested (based on aerial photos) are rarely visited and therefore the proportion of denied-access, hazardous, or inaccessible plots is significantly smaller for them than it is for forested plots.

The poststratification approach outlined in Bechtold and Patterson (2005) removes nonsampled plots from the sample. Estimates are adjusted for plots that are partially nonsampled by increasing the estimates by the nonsampled proportion within each stratum. To reduce the possible bias introduced by nonsampled plots, we delineated five broad strata groups: census water, forested public land, nonforested public land, forested private land, and nonforested private land. Some of these five broad strata groups were further divided into smaller strata to reduce the variance. The tabulation below shows the percentage of denied-access and hazardous/inaccessible plots for each of the five broad strata groups in California, 2001–2005:

Strata group	Total plots	Denied access	Hazardous/inaccessible
<i>Percent</i>			
Census water	460	0	0
Private forest	1,869	12.54	0.54
Private nonforest	2,204	3.33	0.13
Public forest	4,881	0.51	2.18
Public nonforest	324	0.77	1.86
Total	9,738	3.44	1.29

Timber Products Output Survey

The timber products information presented in this report was based on a census of California’s timber processors and out-of-state processors that use California timber. The census was conducted by the University of Montana’s Bureau of Business and Economic Research in cooperation with PNW-FIA (Morgan et al. 2004). Through a written questionnaire or a phone interview, forest products

manufacturers provided the following information for each of their facilities: plant production capacity and employment; volume of raw material received, by county and ownership; species of timber received; finished product volumes, types, sales value, and market locations; and utilization and marketing of manufacturing residue. This survey is designed to determine the size and composition of California's timber harvest and forest products industry, the industry's use of forest resources, and the generation and disposition of wood residues.

National Woodland Owner Survey

This survey of private forest owners is conducted annually by the FIA Program to increase our understanding of private woodland owners. Questionnaires are mailed to individuals and private groups owning woodlands in which FIA has established forest inventory plots. Nationally, 20 percent of these owners (about 50,000) are contacted each year, with more-detailed questionnaires sent to coincide with national census, inventory, and assessment programs. For California, 269 private noncorporate woodland owners were sent questionnaires, and the 124 that were returned provide the data that were summarized and presented in this report.

Periodic Versus Annual Inventories

The PNW-FIA Program began fieldwork for the fifth inventory of California in 2001. This was the first inventory that used the annual inventory system, in which 1/10 of all forested plots (referred to as one panel) were visited each year. The first statewide panel of field plots was completed in 2001. By 2006, half of all field plots in the state had been measured, prompting production of this congressionally mandated 5-year analysis of California's forest resources.

Data from new inventories are often compared with those from earlier inventories to determine trends in forest resources. However, for the comparisons to be valid, the procedures used in the two inventories should ideally be identical. Previous inventories of California's forest resources were completed in 1974, 1983, and 1994. These were periodic inventories in which all timberland plots in the state (outside of national forests and reserved areas

such as national parks) were visited within a 2- or 3-year window. The last periodic inventory on national forests was completed in 1999.

As a result of our ongoing efforts to improve the efficiency and reliability of the inventory and to conform to the national annual inventory design adopted by all FIA units, several changes in procedures and definitions have been made since the last California inventory in 1994. These changes included an increase in plot density of about 18 percent, a new plot footprint (changing from a five-subplot configuration, in which about 2.5 acres were sampled, to a four-subplot configuration in which less than 1 acre is sampled) (fig. 90), a new set of nationally consistent measurement protocols, a plot visitation schedule that calls for sampling of 10 percent of all forested plots in the state each year, and changes in timberland classification protocols. Although these changes will have little impact on statewide estimates of forest area, timber volume, and tree biomass, they have significantly affected estimates of timberland area (see below) and may affect plot classification variables such as forest type and stand size class, especially for estimates at the county level.

Explanation of disparities in timberland area from periodic and annual inventories

Estimates of timberland area from the annual inventory are noticeably larger than timberland estimates from periodic inventories in California. One reason for this is a significant change in the procedures used to classify forest land as either productive timberland or unproductive forest land. In the periodic inventory of the mid 1990s, forest land was often classified using aerial photos or stratified map layers, before plots were assessed in the field. Classifications were based on a number of factors such as species present, density/cover of trees, and geographic location. Timberland is defined as forests capable of producing at least 20 cubic feet/acre/year of continuous crops of commercial trees, where "commercial" is defined in terms of size and quality of roundwood suitable for lumber or other manufactured products. All other forests (those not classified as timberland via aerial photos or field assessment) were assigned one the "unproductive" forest land labels (oak woodland

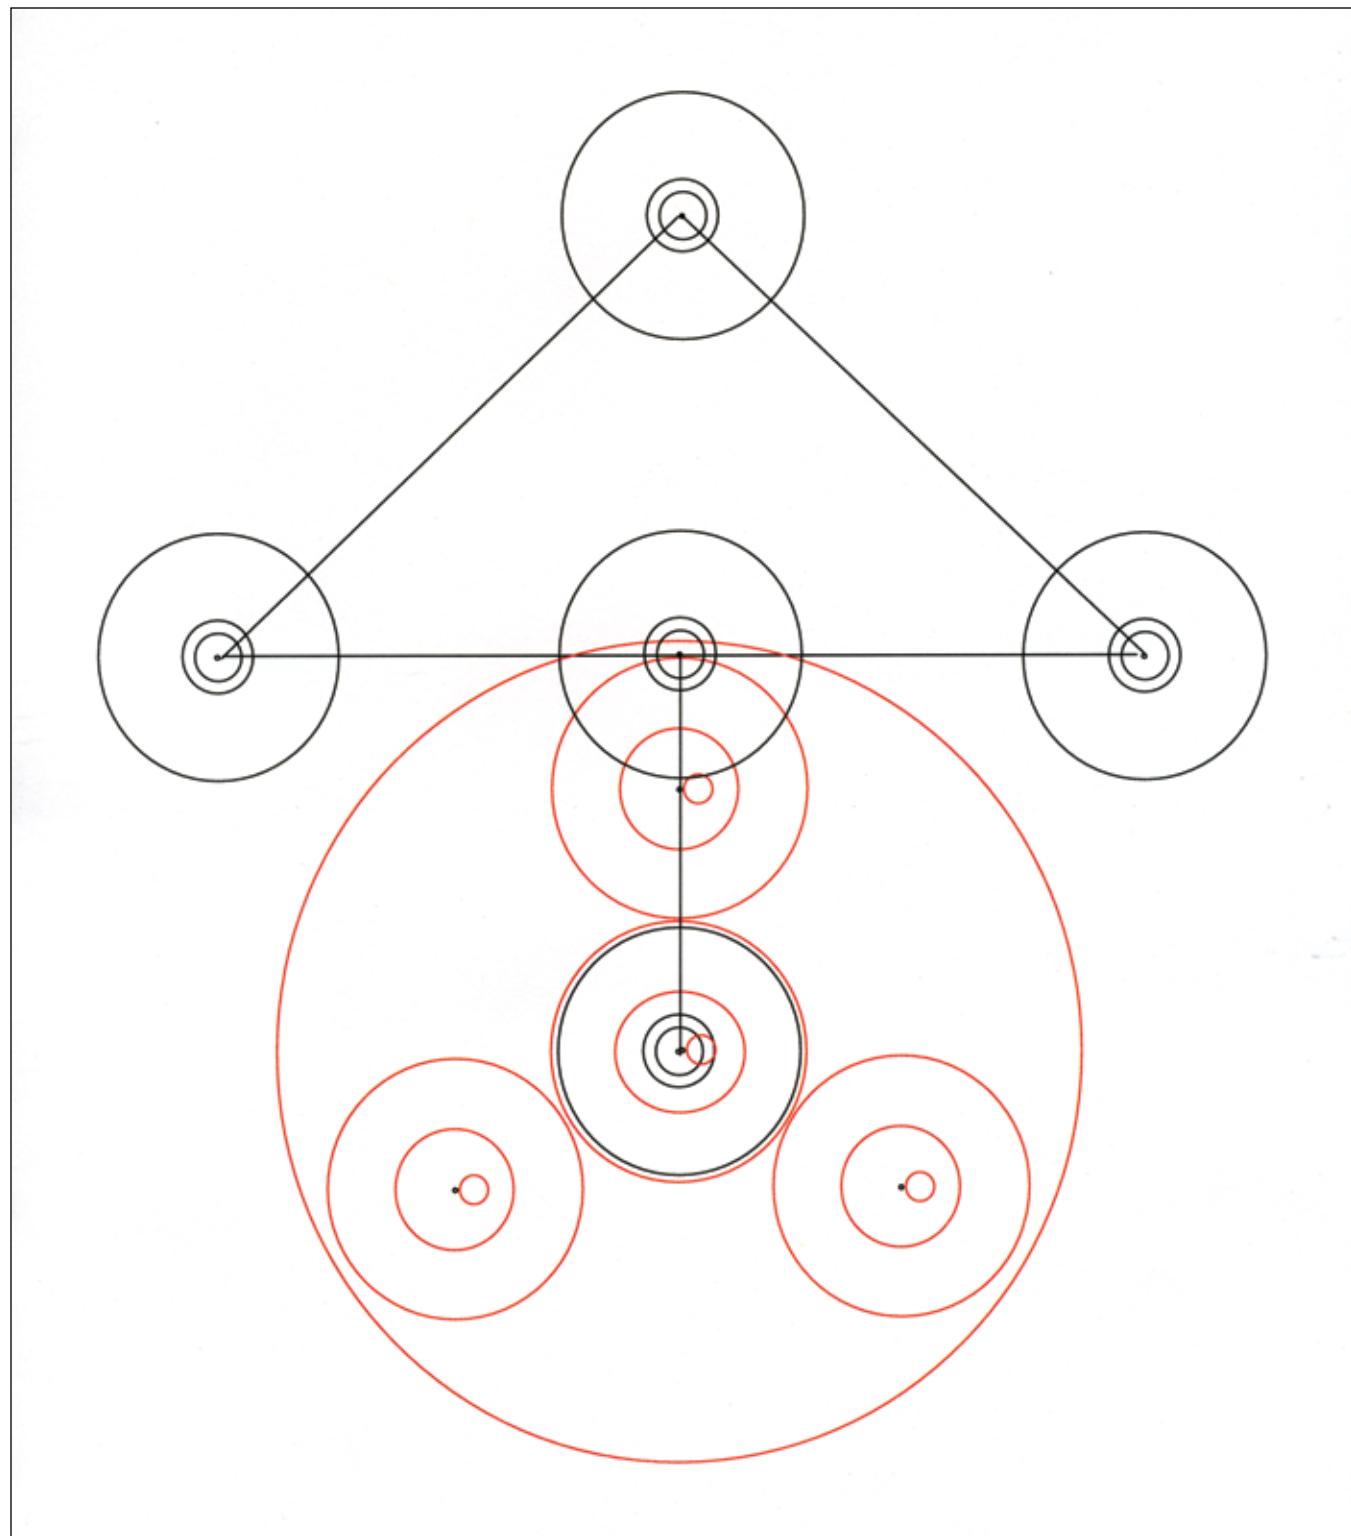

Figure 90—Relationship of periodic (upper, black figure) and annual (lower, red figure) inventory plot designs. Note that only one subplot center overlaps for both designs.

or pinyon-juniper, for example). Site trees were used to determine site index and the associated productivity index (mean annual increment, MAI) on all timberland plots. In some cases, the calculated MAI fell below the 20 cubic feet/acre/year threshold resulting in several plots being reclassified as unproductive forest.

With the intent of developing a more objective approach to classifying forest land, with the advent of annual inventory (which began implementation in California in 2001), FIA began collecting site trees on all forest land, including unproductive land. Instead of subjectively assigning forest land classes via visual inspection (of photos or plots on the ground) or based on the presence or absence of commercial species, site index equations are used to estimate site index and calculate MAI to obtain an objective estimate of productivity. As before, MAI is the basis for assigning a site class to every forest condition on the plot, which, in turn, is used to determine whether forest land is timberland or unproductive forest. Because there are a limited number of site index equations available for each species, and there can be difficulty in locating a representative site tree on some poor sites, the calculated MAI is sometimes unrepresentative of actual productivity. In some cases, conditions previously classified as unproductive forest are now classified as timberland under the new approach, even though it is unlikely that there was any real change in productivity. This has caused a substantial increase in the area of timberland reported in this 5-year summary of the California inventory from 2001 to 2005.

To learn the extent of the various factors that contribute to this issue, a timberland accounting was developed using plots that had been assessed in both the periodic and annual inventories. Using these “paired plots,” the estimate of timberland area from annual inventory date is 2.7 million acres larger than the estimate from the periodic data. About 46 percent of this area was previously classified as oak woodland, 11 percent was pinyon-juniper, 26 percent was other types of forest land, and the rest was nonforests as represented in the periodic inventory data. Although some of these changes may be real and represent actual change, the majority are likely owing to changes in the approach to classifying forest land.

Estimates of growth, removals, and mortality (GRM) are particularly dependant on comparisons between inventories, and thus are most likely to be valid when based on remeasurements of the same plots and trees. Only half of the field plots (5 out of 10 panels) have been visited under the annual system to date, and the increase in plot density means about 18 percent of plots are new (they were not visited during a previous inventory). Unlike the five-subplot, variable-radius design used in the 1995 periodic inventory, the annual inventory uses fixed-radius sampling on four subplots, with only one subplot center coinciding with that of a periodic subplot. Thus, relatively few of the trees sampled at the periodic inventory were remeasured in the annual inventory. Estimates of GRM will eventually improve as the annual inventory becomes fully implemented, and several panels of plots are remeasured.

Appendix 2: Summary Data Tables

The following tables contain basic information about the forest resources of California as they relate to the discussions of current forest issues and basic resource information presented in this report. These tables aggregate data to a variety of levels, including county (fig. 5), ecosection (fig. 6), owner group (fig. 7), survey unit (fig. 8), and forest type, allowing Pacific Northwest Research Station Forest Inventory and Analysis (FIA) inventory results to be applied at various scales and used for various analyses. Many other tables could be generated from the California annual data, but space limits us to a few (60+) key ones. Data are also available for download in nonsummarized form at <http://www.fia.fs.fed.us>.

The national FIA Web site (<http://www.fia.fs.fed.us/tools-data/data/>) contains a tool for querying the California

annual data and generating custom tables or maps. Some of the tables in this appendix contain summaries of regional variables; data for regional variables currently are not included in the national FIA database (FIADB). Additional information on regional variables can be requested from our office by e-mailing Karen Waddell (kwaddell@fs.fed.us).

Please note that information in tables presented and in those generated from the FIADB may differ. As new data are added each year to FIADB, any tables generated from it will be based on the current full set of data in FIADB (e.g., 2001–2006, 2001–2007, etc.), whereas tables in this publication contain data from only 2001–2005. The user can take a snapshot of data from FIADB by selecting the desired years and generating tables that are similar, but probably not identical, to those presented here.

All forest types	14,985	259	2,302	147	1,749	123	19,551	266

Note: Totals may be off because of rounding; data subject to sampling error; SE = standard error; — = less than 500 acres were estimated.

^a Stands with a majority of trees at least 11.0 inches diameter at breast height for hardwoods and 9.0 inches diameter at breast height for softwoods.

^b Stands with a majority of trees at least 5.0 inches diameter at breast height but not as large as large-diameter trees.

^c Stands with a majority of trees less than 5.0 inches diameter at breast height.

^a Dry conifer includes the pinyon/juniper; ponderosa, western white, and lodgepole pines; other softwoods; mixed conifer; and nonstocked forest types. Wet conifer includes the Douglas-fir, fir/spruce/mountain hemlock, hemlock/Sitka spruce, and redwood forest types. Dry hardwood includes the western oak, tanoak/laurel, other hardwoods, and exotic forest types. Wet hardwood includes the elm/ash/cottonwood, aspen/birch, and alder/maple forest types.

^c Gross volume of live trees ≥ 5 inches diameter at breast height.

Table 43—Estimated area of forest land covered by selected nonnative vascular plant species, by life form and species, California, 2001–2005

Plant life form		Area covered	
Scientific name	Common name	Total	SE
<i>Acres</i>			
Shrubs:			
<i>Cytisus scoparius</i>	Scotch broom	3,000	1,400
<i>Hedera helix</i>	English ivy	300	300
<i>Ilex aquifolium</i>	English holly	200	200
<i>Rubus discolor</i>	Himalayan blackberry	34,400	9,100
<i>Rubus laciniatus</i>	cutleaf blackberry	1,400	1,000
Forbs:			
<i>Centaurea solstitialis</i>	yellow star-thistle	32,300	8,100
<i>Cirsium</i>	thistle spp.	21,800	3,600
<i>Cirsium arvense</i>	Canada thistle	1,000	800
<i>Cirsium vulgare</i>	bull thistle	2,000	800
<i>Digitalis purpurea</i>	purple foxglove	100	100
<i>Hypericum perforatum</i>	common St. John's wort	1,800	800
<i>Hypochaeris radicata</i>	hairy cat's ear	500	200
<i>Torilis arvensis</i>	spreading hedgeparsley	23,800	6,300
Grasses:			
<i>Aira caryophyllea</i>	silver hairgrass	14,200	4,000
<i>Avena barbata</i>	slender oat	27,300	9,700
<i>Avena fatua</i>	wild oat	50,000	12,500
<i>Bromus diandrus</i>	ripgut brome	47,100	11,600
<i>Bromus hordeaceus</i>	soft brome	78,800	18,300
<i>Bromus madritensis</i>	compact brome	13,400	6,100
<i>Bromus tectorum</i>	cheatgrass	144,400	17,400
<i>Cynosurus echinatus</i>	bristly dogtail grass	96,000	21,200
<i>Dactylis glomerata</i>	orchardgrass	1,800	1,300
<i>Holcus lanatus</i>	common velvetgrass	100	100
<i>Taeniatherum caput-medusae</i>	medusahead	63,800	14,700

Note: Estimates are likely low for most grasses and some forbs because of short flowering seasons and difficulty of species identification. Data subject to sampling error; SE = standard error.

Table 44—Summary of lichen community indicator species richness on forest land, by location, California, 1998–2001, 2003

Parameter	Location			
	California	Greater Central Valley	Greater Sierra Nevada	Northwest Coast ^a
Number of plots ^b	288	76	133	68

Skunkbush	0	0	254	270	328	262	1,114
Snowberry	170	204	627	776	724	706	3,207
Western wormwood	0	0	30	90	30	30	180
Percentage of forest land by biosite index category ^b							
0 to 4.9 (least injured)	—	—	—	—	—	—	75.7
5.0 to 14.9	—	—	—	—	—	—	22.1
15 to 24.9	—	—	—	—	—	—	2
>25 (most injured)	—	—	—	—	—	—	0.2

Note: — = no value calculated.

^a The biosite index is based on the average injury score (amount × severity) for each species averaged across all species on the plot.

Biosite categories represent a relative measure of tree-level response to ambient ozone exposure.

^b Percentage of forest land is estimated after interpolating the biosite values (2000–2005) to generate a biological response surface across the landscape.

Table 50—Total acres of forest land with a forest fire incident, by year and ecosection group, California, 1995–2004

Table 54—Estimated area of forest land covered by vascular plant nontimber forest products, by plant group and species, California, 2001–2005

Plant group and scientific name	Common name	Total	SE
<i>Acres</i>			
Tree seedlings and saplings:			
<i>Abies magnifica</i>	California red fir	46,700	4,600
<i>Abies procera</i>	noble fir	100	100
<i>Calocedrus decurrens</i>	incense-cedar	99,100	5,900
<i>Crataegus</i> spp.	hawthorn species	1,000	1,000
<i>Juniperus occidentalis</i>	western juniper	16,900	2,000
<i>Pseudotsuga menziesii</i>	Douglas-fir	128,100	6,500
<i>Taxus brevifolia</i>	Pacific yew	2,800	1,000
<i>Thuja plicata</i>	western redcedar	600	400
Shrubs:			
<i>Acer circinatum</i>	vine maple	19,200	5,900
<i>Arctostaphylos columbiana</i>	hairy manzanita	7,000	3,000
<i>Arctostaphylos nevadensis</i>	pinemat manzanita	118,100	15,900
<i>Arctostaphylos patula</i>	greenleaf manzanita	387,500	27,900
<i>Arctostaphylos</i> spp.	manzanita species	87,900	15,500
<i>Arctostaphylos uva-ursi</i>	kinnikinnick	7,000	3,200
<i>Arctostaphylos viscosa</i>	sticky whiteleaf manzanita	226,800	31,100
<i>Ceanothus velutinus</i>	snowbrush ceanothus	116,300	18,600
<i>Chimaphila umbellata</i>	pipsissewa	30,500	3,700
<i>Cytisus scoparius</i>	Scotch broom	3,000	1,400
<i>Eriodictyon californicum</i>	California yerba santa	5,100	1,700
<i>Frangula purshiana</i>	Pursh's buckthorn	5,700	2,100
<i>Gaultheria shallon</i>	salal	83,600	12,400
<i>Mahonia aquifolium</i>	Oregon grape	6,700	2,200
<i>Mahonia nervosa</i>	dwarf Oregon grape	41,300	7,500
<i>Mahonia repens</i>	creeping barberry	500	300
<i>Paxistima myrsinites</i>	Oregon boxleaf	7,900	2,500
<i>Ribes</i> spp.	currant spp.	131,300	10,300
<i>Rosa</i> spp.	rose spp.	39,800	3,800
<i>Sambucus nigra</i>	European black elderberry	2,100	800
<i>Sambucus racemosa</i>	red elderberry	6,100	3,000
<i>Vaccinium membranaceum</i>	thinleaf huckleberry	3,200	1,800
<i>Vaccinium ovatum</i>	California huckleberry	265,000	31,800
Herbs:			
<i>Achillea millefolium</i>	common yarrow	19,100	2,400
<i>Anaphalis margaritacea</i>	western pearly everlasting	1,700	500
<i>Arnica cordifolia</i>	heartleaf arnica	1,300	700
<i>Asarum caudatum</i>	British Columbia wildginger	1,600	500
<i>Equisetum</i> spp.	horsetail spp.	10,300	3,000
<i>Hypericum perforatum</i>	common St. John's wort	1,800	800
<i>Polystichum munitum</i>	western swordfern	176,200	21,700
<i>Pteridium aquilinum</i>	western brackenfern	141,600	14,000
<i>Trillium ovatum</i>	Pacific trillium	400	100
<i>Urtica dioica</i>	stinging nettle	4,000	1,800
<i>Xerophyllum tenax</i>	common beargrass	18,600	5,700

Note: Data subject to sampling error; SE = standard error.

Table 55—Percentage of forested plots with selected lichen nontimber forest products present, by species, California, 2001–2005

Scientific name	Common name	Percent
<i>Alectoria sarmentosa</i>	Witch's hair lichen	13.5
<i>Bryoria fremontii</i>	Old man's beard	13.1
<i>Letharia vulpina</i>	Wolf lichen	53.8
<i>Lobaria pulmonaria</i>	Lungwort	6.9
<i>Parmelia saxatilis</i>	Crottle	1.5
<i>Ramalina menziesii</i>	Lace lichen	2.9
<i>Usnea</i>	Beard lichens	38.2
<i>Usnea hirta</i>	Beard lichen	1.1
<i>Vulpicida canadensis</i>	Brown-eyed sunshine lichen	8.4

Note: Data subject to sampling error; 275 forested plots were sampled.
